ABSTRACT

The Job Portal Management System is a web-based application developed to streamline and automate the recruitment process by enabling efficient interaction between job seekers and employers. The system allows users to securely register and authenticate before accessing portal functionalities, ensuring authorized access to data and services. Job seekers can create and manage their profiles by providing details such as skills, education, and experience, search for suitable job opportunities, and apply for positions that match their interests. Employers can register their organizations, post job vacancies with detailed descriptions, and manage job listings. All user, job, and application-related data are stored and managed using a MySQL database, which ensures structured data organization, data integrity, and efficient retrieval through well-defined primary and foreign key relationships.

The system provides additional features such as job search filtering, application tracking, and application status management to improve transparency and user experience. Employers can review applications submitted by job seekers, shortlist candidates, and update application statuses, while job seekers can track the progress of their applications in real time. The web interface is developed using HTML, CSS, and JavaScript to provide a simple and user-friendly experience, while backend operations such as authentication, job posting, application processing, and database communication are handled using a server-side framework. The Job Portal Management System reduces manual recruitment efforts, minimizes paperwork, improves overall efficiency, and offers a scalable and reliable platform that can be enhanced in the future with features such as email notifications, advanced search options, and recommendation-based job matching.

SYSTEM MODULES

MODULE 1: Job-Seeker

This module provides functionalities for job seekers to create and manage profiles containing personal, educational, and professional details. Users can search and filter job listings based on skills, location, and experience, apply for suitable positions, and track the status of their applications. Resume management and application history are maintained through relational tables.

MODULE 2: Employer

The Employer module enables recruiters to register organizations, post and manage job vacancies, and review applicant profiles. Employers can shortlist candidates, update application statuses, and communicate decisions. Database relationships ensure consistency between job postings, employers, and applicants.

MODULE 3: Job & Application Management

This module manages the creation, storage, and retrieval of job postings and job applications. It connects job seekers and employers by maintaining relationships between users, jobs, and applications. The module tracks application status such as applied, shortlisted, or rejected. It enforces business rules like preventing duplicate applications. All application records are maintained accurately for monitoring and reporting purposes.

MODULE 4: Administrator

The Administrator module provides centralized control over the system. It allows administrators to manage users, monitor job postings, enforce data validation rules, and generate analytical reports. Role-based access control ensures system security and controlled data access
